Data type

Python supports several **built-in data types**, each serving **different purposes**. Data types in Python are used to **represent different kinds** of data and **enable operations** specific to each type. Here are some common use cases for each data type:

1) **Store Value**
2) **Classify the data**
3) **Perform operation**

Type		Example	
Numeric	Int	x = 2	
	float	x = 2.5	
Bool	Bool	x = False	x = True
None	None	abc = None	This means nothing or null
Sequence	String	x= 'rajesh'	**X= "10" , X= '10.5'**
	List	list1 = [1,2]	list1 = ["abc","sameer","Rajesh"]
	Tuple	tup1= (1, 2, 3)	Tup1 = ("abc","sameer","Rajesh")
Set Type	Set	unique_numbers = {1, 2, 3, 4, 5}	
Mapping Type	Dictionary	my_dict = {'key1': 'value1', 'key2': 'value2', 'key3': 'value3'}
