Functions

In Python, a function is a block of **reusable code** that performs a **specific task.** Functions also allow programmers to

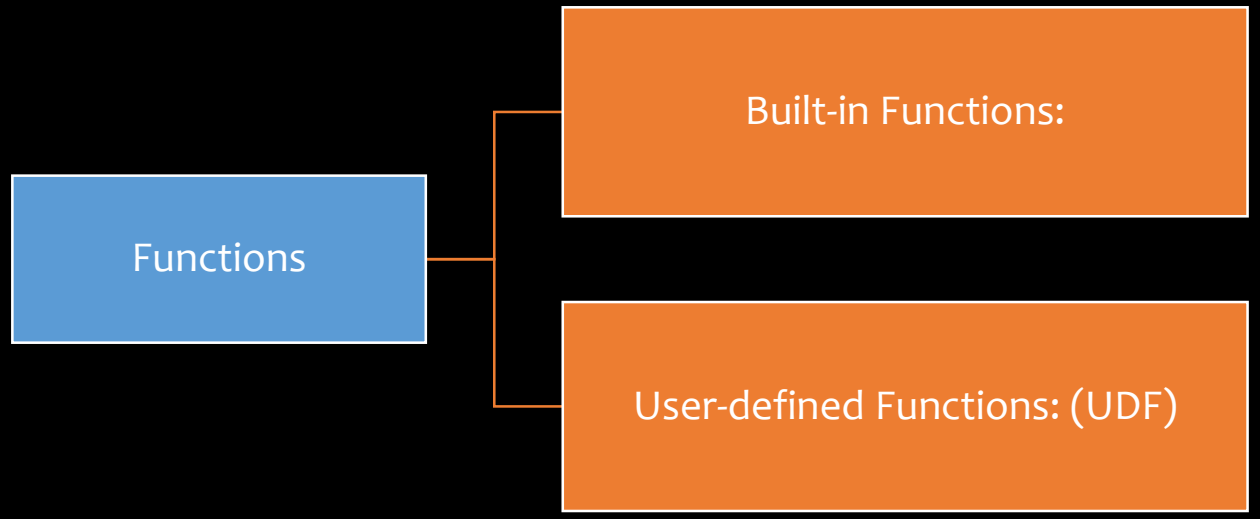

- break down your program into smaller, modular pieces,
- making your code more organized,
- easier to **understand** and easier to **maintain**.
- And it starts with **def** keyword

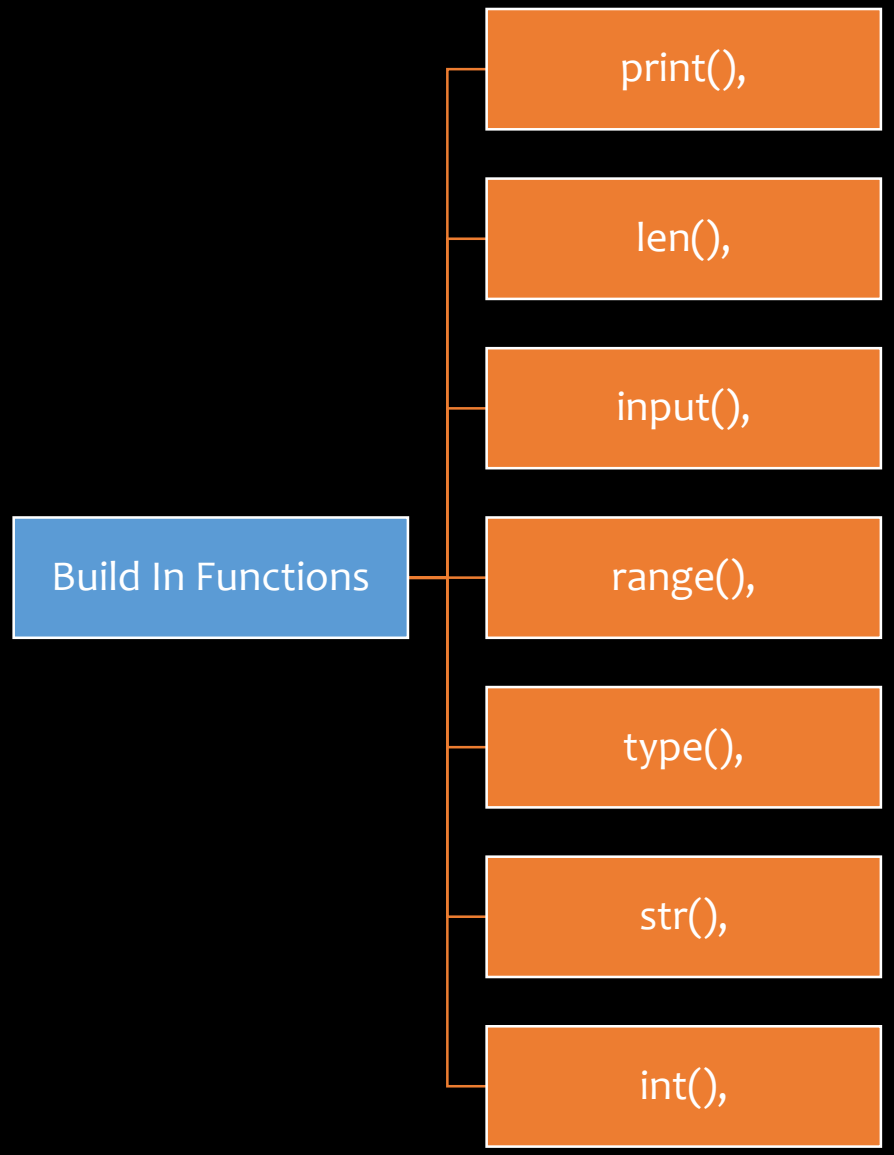

Python functions may contain attributes or logical structure or both.

```
2  def my_function(fname, lname):
3      print(fname + " " + lname)
4
5  my_function("Sunil", "Chavan")
```

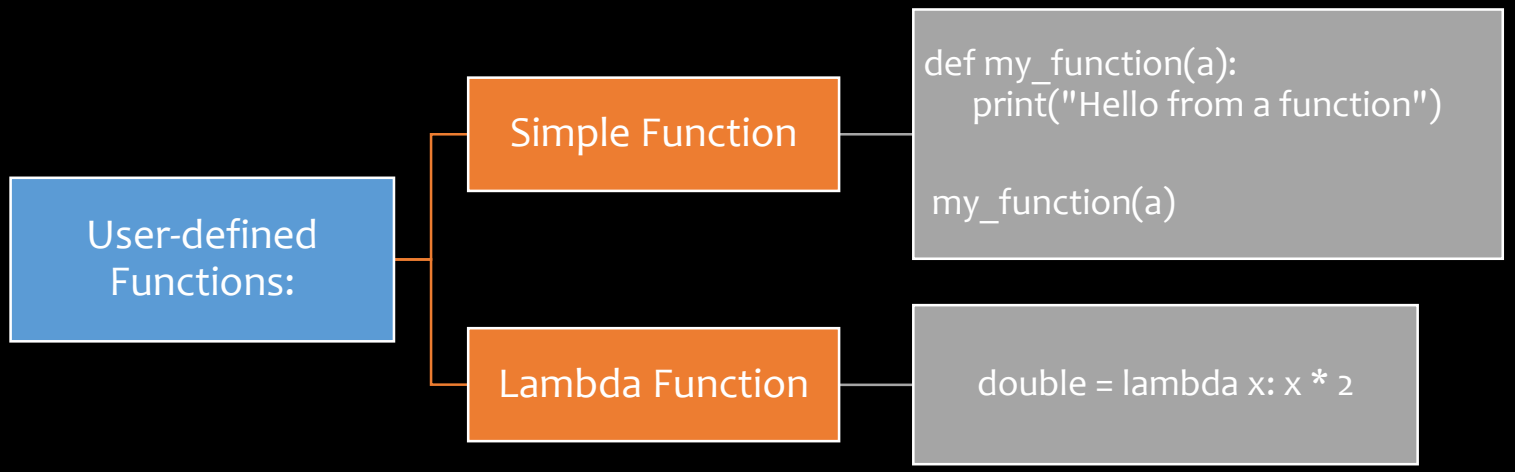

```
Sunil Chavan
```

Different Type of Functions

These are in build functions that are always available in Python, no matter which modules are imported.

User Defined function(UDF)

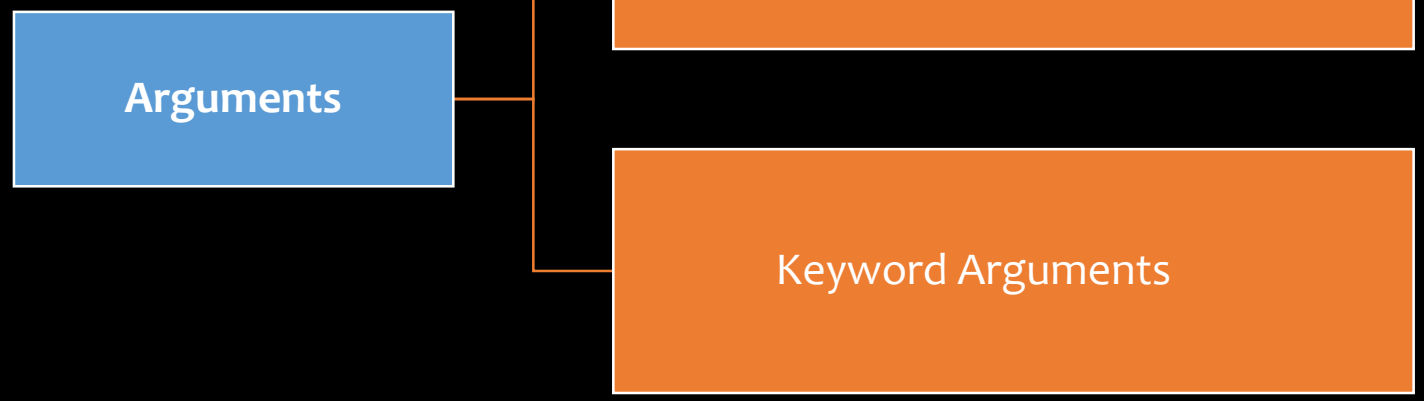

is a block of code that only runs when it is called. You can pass data, known as parameters, into a function. A function can return data as a result. In Python a function is defined using the **def** or **lambda** keyword :

Parameters or Arguments?

A parameter or argument is the variable listed inside the parentheses in the function definition.
Or it is the value that is sent to the function when it is called.

```
2  def my_function(fname, lname):
3      print(fname + " " + lname)
4
5  my_function("Sunil", "Chavan")
```

```
Sunil Chavan
```

```
2  def my_function(fname, lname):
3      print(fname + " " + lname)
4
5  my_function("Sunil", "Chavan")
```

```
Sunil Chavan
```

```
3  def my_function(child3, child2, child1):
4      print("The youngest child is " + child3)
5
6  my_function(child1 = "Raejsh", child2 = "SUnil", child3 = "Savita")
7
```

```
The youngest child is Savita
```

Lambda Functions:

Syntax of lambda function

```
lambda arguments : expression
lambda a         : a + 10

lambda arguments : true_value if condition else false_value
lambda x,y       :     x      if    x>y    else      y
```
